

## Imperative

vs.

## Functional

### Command

- executed
- has an effect

$x := 5$

(state)

### Expression

- evaluated
- no effect

$3 + 4$

(value)

Computation is function.

## Parallelism v.s. Sequential

one can have as many processors as one wants.

$n^2$

→ length of longest critical path?

e.g.  $(3+4) * (2+1)$

→  $\log_2(n)$

sequential: 3 steps

parallel: 2 steps ( $3+4$  &  $2+1$ )

## Types

a prediction about the kind of value an expression will have if it winds up to a value

$\left\{ \begin{array}{ll} \text{well-typed} & \geq 1 \text{ type} \\ \text{ill-typed} & \text{otherwise} \end{array} \right.$

c type-check!

(ML compiler)

c evaluate

expression type value

$e : t \quad e \rightarrow v$

e.g.  $(3+4) * 2 : \text{int}$

$(3+4) * 2 \rightarrow 14$

Type-check  $e_1 + e_2 : \text{int}$  if  $e_1 : \text{int}$  &  $e_2 : \text{int}$

well-typed expression w/out a value :  $5 \text{ div } 0 : \text{int}$

if  $5 > 4$  then 1 else  $5 \text{ div } 0 : \text{int}$

(return 1) (short circuit)

1 div 2 : int return 0

## Extensional Equivalence $\cong$

Expressions are extensionally equivalent if they have the same type and

both  $\left\{ \begin{array}{l} \text{reduce to the same value} \\ \text{or raise to the same exception} \end{array} \right.$

or loop forever

Functions are ... if they map equivalent arguments to equivalent results.

e.g.  $(\text{fn } x \Rightarrow x + x) \cong (\text{fn } y \Rightarrow 2 * y)$

$[2, 7, 6] \cong [1+1, 2+5, 3+3]$

$21 + 21 \cong 42 \cong 6 * 7$

Basic types: int, real, bool, char, string

Constructed types:

## Products

Types  $t_1 * t_2$  for type  $t_1, t_2$

values  $(v_1, v_2)$  for values  $v_1, v_2$

Expressions  $(e_1, e_2), \#1 e, \#2 e$

e.g.  $(3 * 4, \text{true}) : \text{int} * \text{bool}$

## Functions

$f : X \rightarrow Y$  map between types  $X, Y$

$f$  is total if  $f(x)$  returns a value for all values  $x$  in  $X$ .

①  $(* \text{ square} : \text{int} \rightarrow \text{int})$

② REQUIRES: true

③ ENSURES:  $\text{square}(x)$  evaluates to  $x * x$

$*$ )

④  $\text{fun square}(x : \text{int}) : \text{int} = x * x$

⑤  $(* \text{ test cases})$

--

$*$ )

## Declaration

$\text{val } \pi : \text{real} = 3.14$

↑    ↑            ↑  
keyword identifier    type    value

Introduces binding of  $\pi$  to 3.14  $[3.14 / \pi]$

second binding of  $x$  shadows first binding

$\text{val } x : \text{int} = 8 - 5$	{	$[3 / x]$
$\text{val } y : \text{int} = x + 1$		$[4 / y]$
$\text{val } x : \text{int} = 10$		$[10 / x]$
$\text{val } z : \text{int} = x + 1$		$[11 / z]$

## Local Declaration

let ... in ... end

let

val m : int = 3

val n : int = m \* m

in

m + 1

end

} an expression

type? int

value? 12

## Concrete Type Def

type float = real

type point = float \* float

val p : point = (1.0, 2.6)

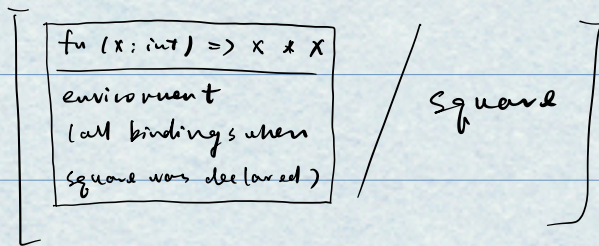

Synonym for existent types

## Closures

Function declarations create value bindings.

`fun square (x: int) : int = x * x` binds the identifier square to a closure { lambda exp  
environment

`fun (x: int) => x * x` lambda expression (anonymous!)

`fun add x (x: int) : int -> int = (fun (y: int) => x + y);`

`> val add x = fun: int -> int -> int`

`->`'s are right associative! `int -> int -> int` same as `int -> (int -> int)`

`val add 5: int -> int = add x 5;`

`> val add 5 = fun: int -> int`

## Functions are values!

`fun f (x: int) = x + 1` is the same as

`val f: int -> int = fun (x: int) => x + 1`

## Type checking Rules

$(\text{fn } (x: t_1) \Rightarrow \text{body}): t_1 \rightarrow t_2$   
if  $\text{body}: t_2$  assuming  $x: t_1$

eg.  $\text{fn } (x: \text{int}) \Rightarrow x+1 : \text{int} \rightarrow \text{int}$   
 $\text{fn } (x: \text{real}) \Rightarrow x+1 : \text{real} \rightarrow \text{real}$

## Evaluation Rules: $es \rightarrow v$

- 1) Reduce  $es$  to a (function) value.
- 2) Reduce  $es$  to a value  $v$  <sup>a closure with lambda exp & env</sup>
- 3) Extend env with binding  $[v/x]$
- 4) Evaluate body in this extended environment

## Function Clauses & Pattern

$\text{fun } f \text{ } p_1 = e_1$   
 $\quad | \text{ } f \text{ } p_2 = e_2$   
 $\quad \vdots$   
 $\quad | \text{ } f \text{ } p_k = e_k$

pattern      expression

SMR will try to match  $v$  against  $p_1$ , then  $p_2 \dots$  until a match  $p_j$  succeeds  $\rightarrow$  SMR evaluates  $e_j$ .

If no pattern matches  $v \rightarrow$  fatal runtime error

pattern  $\left\{ \begin{array}{l} \text{constant} \\ \text{variable} \\ \text{subpatterns} \\ \text{wild card - (matches anything)} \end{array} \right.$

eg.  $(\text{fn } (0: \text{int}) \Rightarrow \text{"good"} \mid (1: \text{int}) \Rightarrow \text{"so so"} \mid (-: \text{int}) \Rightarrow \text{"nope"})$

$\text{fun silly } (x: \text{int}): \text{int} = 1 \mid \text{silly } (0: \text{int}) = 0 \rightarrow \text{error!}$   
redundant  
 $f_{-1} = 0$

$\text{fun fibb } (0: \text{int}): \text{int} \times \text{int} = (1, 0)$

## Passing a function

$\text{fun sqrf } (f: \text{int} \rightarrow \text{int}, x: \text{int}): \text{int} = \text{square}(f(x))$
